Modular Approach

- "/usr/include" directory is called standard directory for header files.
- It contains all the standard header files of C/C++
- If we include header file in angular bracket (e.g #include<filename.h>) then preprocessor try to locate and load header file from standard directory only(/usr/include).
- If we include header file in double quotes (e.g #include"filename.h") then preprocessor try to locate and load header file first from current project directory if not found then it try to locate and load from standard directory.

Header Guard

```
#ifndef HEADER_FILE_NAME_H_
#define HEADER_FILE_NAME_H_
//TODO : Type declaration here
#endif
```

Reference

- Reference is derived data type.
- It alias or another name given to the exisiting memory location / object.
 - Example : int a=10; int &r = a;
 - In above example a is referent variable and r is reference variable.
 - It is mandatory to initialize reference.
- Reference is alias to a variable and cannot be reinitialized to other variable
- When '&' operator is used with reference, it gives address of variable to which it refers.
- Reference can be used as data member of any class
- Using typedef we can create alias for class whereas using reference we can create alias for object.

Reference

- We can not create reference to constant value.
 - int &num2 = 10; //can not create reference to constant value
- Reference is internally considered as constant pointer hence referent of reference must be variable/object.

```
int main( void )
       int num1 = 10;
       int &num2 = num1;
       //int *const num2 = &num1;
       cout<<"Num2 : "<<num2<<endl;
       //cout<<"Num2 : "<<*num2<<endl;
       return 0;
```

pass arguments to function, by value, by address or by reference.

- In C++, we can pass argument to the function using 3 ways:
- 1. By Value
- 2. By Address
- 3. By Reference
- If variable is passed by reference, then any change made in variable within function is reflected in caller function.
- Reference can be argument or return type of any function

Static Variable

- All the static and global variables get space only once during program loading / before starting execution of main function
- Static variable is also called as shared variable.
- Unintialized static and global variable get space on BSS segment.
- Intialized static and global variable get space on Data segment.
- Default value of static and global variable is zero.
- Static variables are same as global variables but it is having limited scope.

Static Member Functions

- Except main function, we can declare global function as well as member function static.
- To access non static members of the class, we should declare member function non static and to access
- static members of the class we should declare member function static.
- Member function of a class which is designed to call on object is called instance method. In short non static member function is also called as instance method.
- To access instance method either we should use object, pointer or reference to object.
- static member function is also called as class level method.
- To access class level method we should use classname and ::(scope resolution) operator.

Dynamic Memory Allocation

- If we want to allocate memory dynamically then we should use new operator and to deallocate that memory we should use delete operator.
- If pointer contains, address of deallocated memory then such pointer is called dangling pointer.
- When we allocate space in memory, and if we loose pointer to reach to that memory then such wastage of memory is called memory leakage.

Thank You
